

[1] Reactions in solutions: acid-base titrations (12 pts)

[1](a) Phosphorus trifluoride (PF_3) is a highly toxic gas that reacts slowly with water to give a mixture of phosphorous acid (H_3PO_3) and hydrofluoric acid (HF). The balanced chemical equation for this reaction is:

Please determine the concentration of each of the acids that result from the complete reaction of 4.94 L of PF_3 (measured at 25°C and 0.970 atm pressure; PF_3 is in gaseous phase at this P-T) with enough water to give a solution volume of 872 mL.

$$PV = nRT \quad 0.970 \times 4.94 = n = 0.0769 \text{ mol } \text{PF}_3$$

$$\begin{aligned} P &= 0.970 \\ T &= 298.15 \text{ K} = 25^\circ\text{C} \\ V &= 4.94 \text{ L} \\ n &= ? \end{aligned}$$

$$0.0769 \times 298.15$$

$$= 0.0769 \text{ mol } \text{H}_3\text{PO}_3$$

$$= 3(0.0769) \text{ mol } \text{HF}$$

$$= 0.2307 \text{ mol } \text{HF}$$

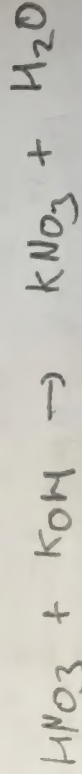

$$1 : 1 : 3$$

$$\text{Volume} = 0.872 \text{ L} = 872 \text{ mL}$$

$$\text{Conc } \text{HF} = \frac{0.2307}{0.872} = 0.265 \text{ M } \text{HF}$$

$$\text{Conc } \text{H}_3\text{PO}_3 = \frac{0.0769}{0.872} = 0.0882 \text{ M } \text{H}_3\text{PO}_3$$

[1](b) To determine the concentration of a sample solution of nitric acid (HNO_3), a 100.0-mL sample is placed in a flask and titrated with a 0.1279 M solution of KOH (aq). A volume of 37.85 mL KOH (aq) is required to reach the phenolphthalein end point. Please calculate the concentration of nitric acid in the original sample.

$$M_A V_A = M_B V_B \quad \text{Conc} \times \text{Vol} = \text{mol}$$

$$M_A$$

$$V_A = 0.1 \text{ L}$$

$$M_B = 0.1279 \text{ M}$$

$$V_B = 0.03785 \text{ L}$$

$$M_A \times 0.1 \text{ L} = 0.1279 \text{ M} \times 0.03785 \text{ L}$$

$$M_A \times 0.1 \text{ L} = 0.00484$$

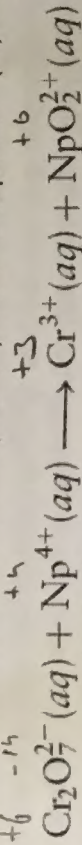

$$M_A = \frac{0.00484}{0.1 \text{ L}} = M_A = 0.0484 \text{ M}$$

$$\text{HNO}_3 \text{ Conc} = 0.0484 \text{ M}$$

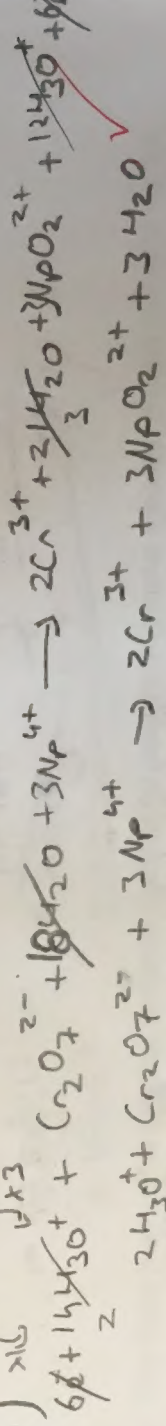

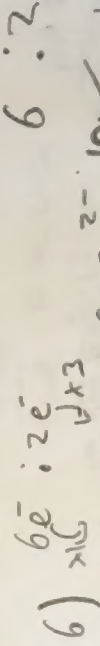

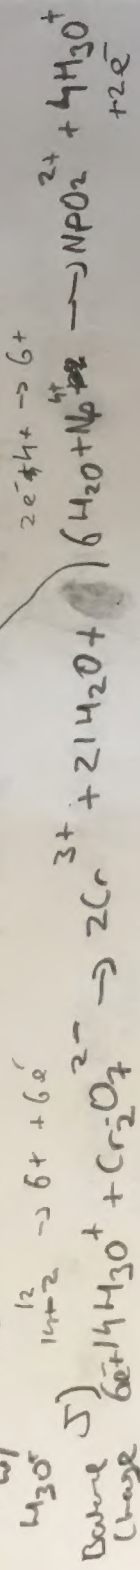

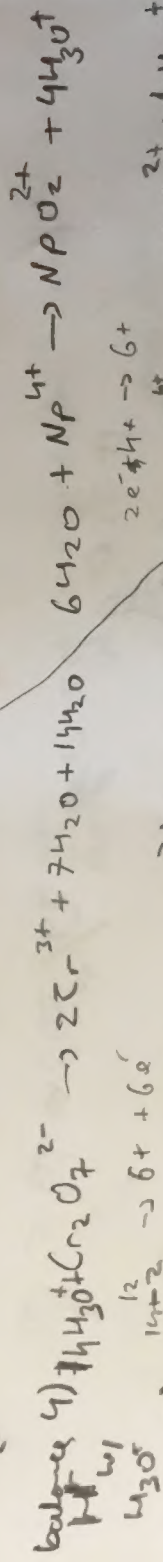

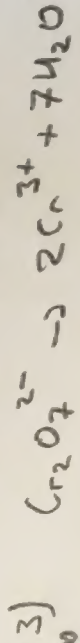

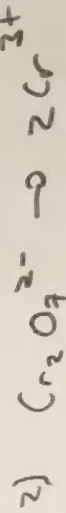

12

[2] Reactions in solutions: redox titrations (12 pts)

For the following redox reaction between dichromate ($\text{Cr}_2\text{O}_7^{2-}$) ions and neptunium (IV) ions, Np^{4+} , in an acidic solution:

[2](a) Please follow the 6 steps listed in the formula sheet to balance this oxidation-reduction reaction. **Please clearly show all 6 steps.**

[2](b) A sodium dichromate ($\text{Na}_2\text{Cr}_2\text{O}_7$) solution is prepared by dissolving 5.000 g of $\text{Na}_2\text{Cr}_2\text{O}_7$ in water and diluting to a total volume of 50.00 mL. A total of 32.50 mL of this solution is required to reach the end point in a titration of 100.0-mL sample containing Np^{4+} (aq). Please calculate the concentration of Np^{4+} in the original solution.

$$\frac{5.000\text{g}}{\text{M}_{\text{Na}_2\text{Cr}_2\text{O}_7}} = \frac{5}{261.1473} = 0.01909 \text{ mol Na}_2\text{Cr}_2\text{O}_7$$

$$\frac{0.01909 \text{ mol}}{0.05 \text{ L}} = 0.3817 \text{ M}$$

$$32.50 \text{ mL} = 0.0325 \text{ L}$$

$$0.3817 \times 0.0325 \text{ L} = 0.0124 \text{ mol}$$

$$= 0.0124 \text{ mol Na}_2\text{Cr}_2\text{O}_7$$

$$0.0124 \text{ mol} \times 3 = 0.0372 \text{ mol Np}^{4+}$$

$$= 0.03722 \text{ mol Np}^{4+}$$

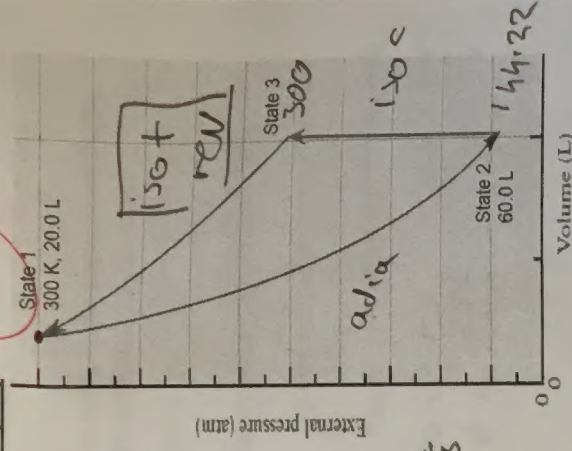

$$\text{Vol Np}^{4+} = 0.1 \text{ L}$$

$$\text{conc} = \frac{\text{mol}}{\text{Vol}} = \frac{0.03722}{0.1} = 0.3722 \text{ mol/L Np}^{4+}$$

12

[4] The first law of thermodynamics: ideal gas processes (part I) (14 pts)

A system containing 2 mol of a monoatomic ideal gas is taken through the cycle in the right diagram in the direction indicated by the arrows: an **adiabatic reversible expansion** from state 1 to state 2, an **isochoric** (constant V) **heating** from state 2 to state 3, and an **isothermal reversible compression** from state 3 back to state 1. Let's work on this ideal gas cycle in questions [4] and [5].

[4](a) Please calculate the temperature of this monoatomic ideal gas system at state 2, T_2 . (Hint: state 1 to state 2 is an **adiabatic reversible process**; you can also find useful information on the diagram.)

$$T_1 = 300 \text{ K} \quad \gamma = 20.04 \quad \gamma - 1 = \frac{C_p}{C_v} - 1 = \frac{5/2}{3/2} - 1 = \frac{2}{3}$$

$$T_1 V_1^{\gamma-1} = T_2 V_2^{\gamma-1}$$

$$300 \times 20^{\frac{2}{3}} = T_2 (60)^{\frac{2}{3}}$$

$$\frac{2210}{60^{\frac{2}{3}}} = T_2 = 144.22 \text{ K}$$

[4](b) Please calculate q , w , ΔU , and ΔH for this **adiabatic reversible expansion** from state 1 to state 2.

adiabatic: $q = 0$

$$\Delta H = n C_p \Delta T$$

$$\Delta U = n C_v \Delta T$$

$$w = n C_v \Delta T$$

$$T_2 - T_1 = 144.22 - 300 = -155.78$$

$$\Delta H = 2 \times \frac{5}{2} \times 8.3145 \times -155.78 = -6476 \text{ J}$$

$$\Delta U = 2 \times \frac{3}{2} \times 8.3145 \times -155.78 = -3885.69 \text{ J}$$

$$w = \Delta U = -3885.69 \text{ J}$$

[4](c) Please calculate q , w , ΔU , and ΔH for the **isochoric heating** from state 2 to state 3.

isochoric $\Delta V = 0 \quad w = 0$

$$\Delta U = q = n C_v \Delta T$$

$$\Delta H = n C_p \Delta T$$

$$q = n C_v \Delta T$$

$$T_2 = 300 \text{ K} \quad T_3 = 144.22 \text{ K}$$

$$w = 0$$

$$\Delta U = 2 \times \frac{3}{2} \times 8.3145 \times (300 - 144.22 \text{ K})$$

$$\Delta U = 3885.69 \text{ J} = q = 3885.69 \text{ J}$$

$$\Delta H = 2 \times \frac{5}{2} \times 8.3145 \times (300 - 144.22) = 6476 \text{ J}$$

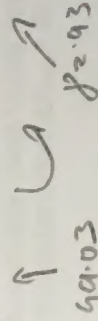

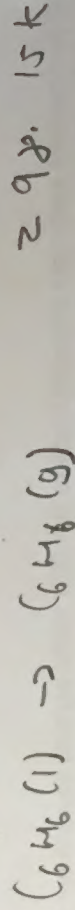

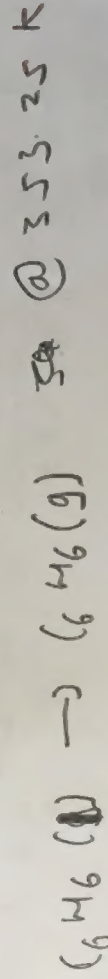

$$w = 0$$

[6] Thermochemistry (12 pts)

Using the information provided below, please calculate the enthalpy change for the reaction:

benzene (l) \rightarrow benzene (g)
at its normal boiling point (80.1 °C and 1 atm). You can treat the molar heat capacities as temperature-independent.

Substance	ΔH_f° (25°C) kJ mol ⁻¹	S° (25°C) J K ⁻¹ mol ⁻¹	ΔG_f° (25°C) kJ mol ⁻¹	C_p (25°C) J K ⁻¹ mol ⁻¹
C ₆ H ₆ (g)	82.93	269.2	129.66	81.6
C ₆ H ₆ (l)	49.03	172.8	124.50	136

$$q_{p1} = n C_p \Delta T = 1 \times 136 \times (T_f - T_i) = 136 \times (298.15 - 353.25)$$

$$(L) \quad \quad \quad 136 \times -55.1 = -7493.6 J$$

$$q_{p2} = n C_p \Delta T = 1 \times 81.6 \times (353.15 - 298.15)$$

$$(g) \quad \quad \quad 81.6 \times 55.1 = 4496.16 J$$

$$\Delta H = \sum n_i \text{ products} - \sum n_j \text{ reactants} = 1 \times 82.93 - 1 \times 49.03$$

$$= 33.9 kJ$$

$$q_p + \Delta H + q_{p2} = \Delta H_{vap} \quad 353.25 K \quad 33900 J$$

$$-7493.6 J + 4496.16 J + 33.9 kJ$$

$$-7493.6 J + 4496.16 J + 33,900 J = 30,902.56 J$$

$$= 30.9 kJ$$

- Prof. U

[7] The second and third laws of thermodynamics (8 pts)

When heating 1.00 mol of **solid benzene** from 5.53 °C to 80.1 °C at 1 atm to reach a final state of **completely gaseous benzene**, it undergoes two phase transitions: melting (at 5.53 °C) and evaporation (at 80.1 °C). The molar enthalpy of fusion of benzene at its normal melting point is 9.9 kJ mol⁻¹, and you have calculated the molar enthalpy of vaporization at its normal boiling point in [6].

[7](a) Please calculate the entropy change when 1.00 mol of solid benzene melts reversibly at its normal melting point, ΔS_{fus} .

$$\Delta S = \frac{q_{\text{rev}}}{T} = \frac{\Delta H_{\text{fus}}}{T_f} = \frac{9.9 \text{ kJ}}{5.53^\circ\text{C}} = \frac{9900 \text{ J}}{278.68 \text{ K}} = 35.5 \text{ J K}^{-1}$$

4/4

[7](b) Please calculate the entropy change when 1.00 mol of liquid benzene vaporizes reversibly at its normal boiling point, ΔS_{vap} . (Hint: Remarkably, most liquids have similar values for the molar entropy of vaporization. Trouton's rule summarizes this observation: $\Delta S_{\text{vap}} = 88 \pm 5 \text{ J K}^{-1} \text{ mol}^{-1}$) $T_b = 80.1^\circ\text{C} = 353.25 \text{ K}$

$$\Delta S = \frac{q_{\text{rev}}}{T}$$

$$\Delta S_{\text{vap}} = \frac{\Delta H_{\text{vap}}}{T_b}$$

$$\Delta S_{\text{vap}} \times T_b = \Delta H_{\text{vap}} \times 1 \text{ mol}$$

take ΔS_{vap}
to be $88 \pm 5 \text{ J K}^{-1} \text{ mol}^{-1}$
by Trouton's rule

$$88 \text{ J K}^{-1} \text{ mol}^{-1} \times 353.25 = 31086 \text{ J}$$

$$= 31.086 \text{ kJ}$$

Using
Trouton's rule

$$\Delta S = 87.48 \text{ J K}^{-1}$$

$$(\pm 1766.25 \text{ J})$$

$$\Delta H_{\text{vap}} = 30.9 \text{ kJ mol}^{-1}$$

$$\Delta H_{\text{vap}} = 30.9 \text{ kJ}$$

$$\Delta S = \frac{\Delta H_{\text{vap}}}{T} = \frac{30.9 \text{ kJ} \times 1000 \text{ J/kJ}}{353.25 \text{ K}} = 87.48 \text{ J K}^{-1}$$

$$= \Delta S_{\text{vap}} 88 \pm 5 \text{ J K}^{-1} \text{ mol}^{-1}$$

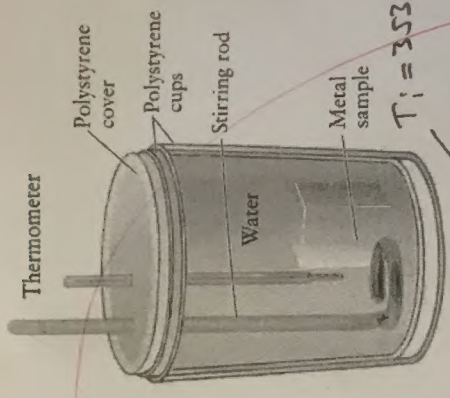

$$\frac{30,900 \text{ J}}{353.25 \text{ K}}$$

Answer

— Prof. U

[8] Entropy changes and spontaneity (14 pts)

From our daily life experience, we know that when a hot body contacts with a cold body, heat will spontaneously flow from the hot body to the cold body, until the temperature of the two bodies reaches the same (thermal equilibrium). Let's use the following example to find the driving force of this spontaneous process.

[8](a) A piece of iron weighing 50.0 g is heated to 80 °C and plunged into 100.0 g water that is initially at 10 °C in a Styrofoam cup calorimeter. Assume no heat is lost to the Styrofoam cup or to the environment. Please calculate the final temperature that is reached. Please take $c_{p,m}$ (Fe) to be $25.1 \text{ J K}^{-1} \text{ mol}^{-1}$ and $c_{p,m}$ (H_2O) to be $75.3 \text{ J K}^{-1} \text{ mol}^{-1}$, independent of temperature.

using $n C_p \Delta T = q_p$ $g \rightarrow \text{mol}$ $T_i = 353.15 \text{ K}$

Fe: $0.895 \times 25.1 \times (T_f - 353.15)$ $\text{mol Fe} = \frac{50}{55.845} = 0.895 \text{ mol Fe}$

$-(22.473(T_f - 353.15))$ $\text{mol H}_2\text{O} = \frac{100}{18.0152} = 5.55 \text{ mol H}_2\text{O}$

$\text{H}_2\text{O} = 55.5 \times 75.3(T_f - 283.15)$ $T_i = 283.15$

$417.98(T_f - 283.15)$ $\rightarrow 5$ $= -22.473 T_f + 7936$

$417.98(T_f - 283.15) = 22.473(T_f - 353.15)$ $T_f = \frac{126287}{440.45} = 286.72$

$T_f = 286.72 \text{ K}$

[8](b) Please calculate the entropy change for the iron, ΔS_{Fe} , the entropy change for the water, $\Delta S_{\text{H}_2\text{O}}$, and ΔS_{tot} in this process.

$S_{\text{Fe}} \rightarrow \Delta S_{\text{Fe}} = \frac{q_{\text{rev}}}{T} = n C_p \ln \frac{T_2}{T_1}$ $\times 25.1 \text{ J K}^{-1} \text{ mol}^{-1}$

$\rightarrow \Delta S_{\text{H}_2\text{O}} = \frac{-\Delta H}{T} = n C_p \ln \frac{T_2}{T_1}$ $= 0.895 \times \ln \left(\frac{286.72}{353.15} \right) \times 25.1 \text{ J K}^{-1} \text{ mol}^{-1}$

$\Delta S_{\text{Fe}} = -4.68 \text{ J K}^{-1}$ $\Delta S_{\text{H}_2\text{O}} = 5.236 \text{ J K}^{-1}$ $\rightarrow \Delta S_{\text{tot}} = \Delta S_{\text{Fe}} + \Delta S_{\text{H}_2\text{O}} = -4.68 + 5.236 = 0.555 \text{ J K}^{-1}$

[8](c) Is this cooling process of iron spontaneous? Please reason your answer using your calculation in [8](b).

This process is spontaneous. $\Delta S_{\text{tot}} > 0$, the process is irreversible and spontaneous as $\Delta S_{\text{tot}} = 0.555 \text{ J K}^{-1}$
